1 Introduction

THis paper uses methods from topology and category theory to develop a model of the transformation from data to graphical representation. This model provides a language to specify how data is structured and how this structure is carried through in the visualization, and serves as the basis for a functional approach to implementing visualization library components. Topology allows us to describe the structure of the data and graphics in a generalizable, scalable, and trackable way. Category theory provides a framework for separating the transformations implemented by visualization libraries from the various stages of visualization and therefore can be used to describe the constraints imposed on the library components [**?**], [**?**]. Well constrained modular components are inherently functional [**?**], and a functional framework yields a library implementation that is likely to be shorter, clearer, and more suited to distributed, concurrent, and on demand tasks [**?**]. Using this functional approach, this paper contributes a practical framework for decoupling data processing from visualization generation in a way that allows for modular visualization components that are applicable to a variety of data sets in different formats. is it OK that this is something reviewer 4 wrote

2 Related Work

This work aims to develop a model for describing visualization transformations that can serve as guidance for how to architecture a general purpose visualization library. We define a general purpose visualization library as one that provides non domain specific building block components [**?**] for building visualizations, for example functions for converting data to color or encoding data as dots. In this section, we describe how visualization libraries attempt this goal and discuss work that formally describes what properties of data should be preserved in a visualization. We restrict the properties of data that should be preserved to

continuity how elements in a dataset are connect to each other, e.g. discrete rows in a table, networked nodes, pixels in an image, points on a line

equivariance functions on data that have an equivalent effect on the graphical representation, e.g. rotating a matrix has a matching rotation of the image, translating the points on a line has a matching visual shift in the line plot

2.1 Continuity

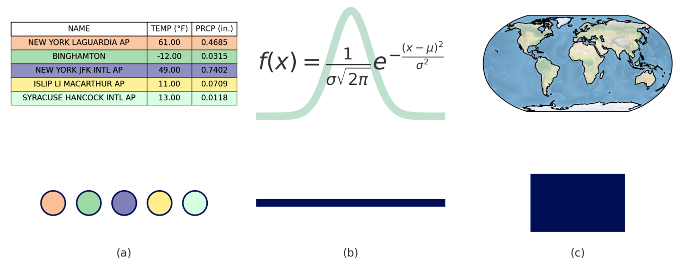

Fig. 1: Continuity is how elements in a data set are connected to each other, which is distinct from how the data is structured. The rows in (a) are discrete, therefore they have discrete continuity as illustrated by the discrete dots. The gaussian in (b) is a 1D continuous function, therefore the continuity of the elements of the gaussian can be represented as a line on an interval (0,1). In (c), every element of the globe is connected to its nearest neighbors, which yields a 2D continuous continuity as illustrated by the square.

We propose that a robust model of continuity, which is how the elements in a dataset are connected to each other, provides a way to develop library components that finish this sentence in a sensible way

For example, in **??**, each station record in the table is independent of the others; therefore, the continuity of the table is discrete. The data provided by the gaussian are points sampled along the curve, therefore the continuity of the points on the line is 1D continuous. Every point on the globe is connected to its 6 nearest cardinal neighboring points (NW, N, NE, E, SE, S, SW, W).

The preservation of continuity can be made explicit, as in the transformation of table to parallel coordinates

Fig. 2: Continuity is implicit in choice of visualization rather than explicitly in choice of data container. The line plots in (b) are generated by a 2D table (a). Structurally this table can be identical to the 2D matrix (a) that generates the image in (c).

in Ruchikachorn and Mueller [?], but is often expressed implicitly in the choice of visual algorithm (visualization type), as explored in taxonomies by Tory and Möller [?] and Chi [?].

For example, in **??** the same table can be interpreted as a set of 1D continuous curves when visualized as a collection of line plots or as a 2D surface when visualized as an image. This means that often there is no way to express data continuity independent of visualization type, meaning most visualization libraries will allow, for example, visualizing discrete data as a line plot or an image. General purpose visualization libraries-such as Matplotlib [?], Vtk [?], [?], and D3 [?]-carry distinct data models as part of the implementation of each visual algorithm. The lack of unified data model means that each plot in a linked [?], [?] visualization is treated as independent, as are the transforms converting each field in the data to a visual equivalent.

Domain specific libraries can often guarantee consistency because they have a single model of the data in their software design, as discussed in Heer and Agarwal [?]'s survey of visualization software design patterns. For example, the relational database is core to tools influenced by APT, such as Tableau [?], [?], [?] and the Grammar of Graphics [?] inspired ggplot [?], Vega [?] and Altair [?]. Images underpin scientific visualization tools such as Napari [?] and ImageJ [?] and the digital humanities oriented ImagePlot [?] macro; the need to visualize and manipulate graphs has spawned tools like Gephi [?], Graphviz [?], and Networkx [?].

2.1.1 Fiber Bundles

The model described in this work provides a method for expressing different types of continuities and nested continuities using the same model. We obtain this generality by using the mathematical theory of fiber bundles as the basis of our abstraction, as proposed by Butler, Bryson, and Pendley [?], [?]. In this paper, we build on their work that proposes using topological spaces to represent different properties of data.

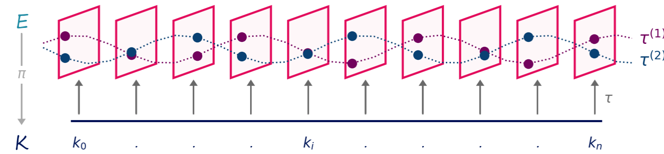

Fig. 3: A fiber bundle is mathematical construct that allows us to express the relationship between data and continuity. The total space Eis the topological space in which the data is embedded. The fiber space F is embedded in E and is the set of all possible values that any add big rectangle E

Specifically, Butler, Bryson, and Pendley suggest that fiber bundles be the basis of an abstract data model. Fiber bundles are a collection of topological spaces.

Definition 2.1. A topological space $(X, \mathscr{T})$ is a set X with a topology $\mathscr{T}$. Topologies are collections of open sets U such that the empty set and X are in the collection of open sets $\mathscr{T}$, the union of elements in $\mathscr{T}$ finish out this definition

Here we present a very brief summary of topics, for more information see Hatcher [?], Munkres [?], and Bradley et. al. [?].

Total Space E
Fiber Space F
Base Space K

with a projection map $\pi : E \rightarrow K$ that connects every point in E to a point in K.

$$F \hookrightarrow E \xrightarrow{\pi} K \tag{1}$$

As indicated by $\hookrightarrow$, the fiber space F is embedded inside the total space EṪhis is illustrated in **??**, wherein values lives in the fiber $F \subseteq E$. In this example, the fiber F is the cartesian product of two sets $F_0 \times F_1$ where each fiber F_i is ....

$$formalequationofthefiber? \tag{2}$$

While the values are embedded in F, the continuity of the data is modeled as the base space K, which is the quotient space [?]

$$formalmathofthebasespaceasequivalenceclassforF_{[}k] \tag{3}$$

which means that every point in F_k maps to a point $k \subset K$.

$$\begin{tikzcd} F \arrow[r, hook] & E \arrow[d, shift right, "\pi"'] \\ & K \arrow[u, bend right, "\tau"'] \end{tikzcd} \tag{4}$$

Throughout this paper, we denote fiber bundles with the tuple $(\mathtt{totalspace}, \mathtt{basespace}, \pi, \mathtt{fiberspace})$

2.2 Equivariance

When introducing the retinal variables, Bertin informally specifies that continuity is preserved in the mark and defines equivariance constraints in terms of data and visual variables being selective, associative, ordered, or quantitative [?]. In the *A Presentation Tool*(APT) model, Mackinlay embeds the continuity constraint in the choice of visualization type and generalizes the equivariance constraint to preserving a binary operator from one domain to another. The algebraic model of visualization [?], proposed by Kindlmann and Scheidegger, restricts equivariance to invertible transformations.

something about how structure of data field serves as basis of equivariance in viz literature Besides expressing continuities, fiber bundles also provide us a way to richly express the structure of the fields in the data. Specifically, we do this by adopting Spivak's formulation of the fiber as a (column name, data domain) simple schema [?], [?]. Spivak formally maps column names and field types to the set of values associated with the field type, for example $\mathbb{R}$ for a `float` column named *temperature*. In the paper, the F is the cartesian cross product of the fibers for each column.

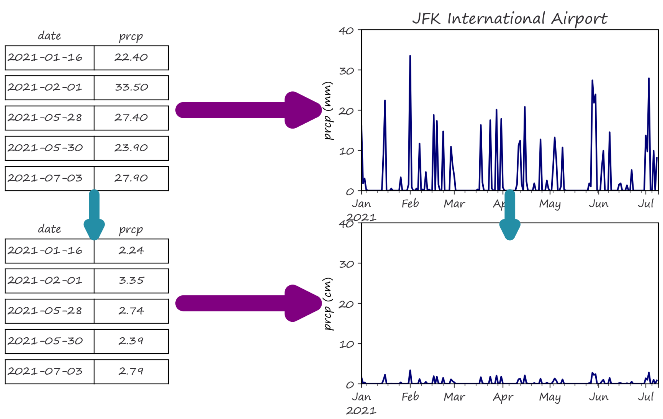

Fig. 4: Equivariance is that a transformation on the data has a corresponding transformation in the graphical representation. For example, in this figure the data is scaled by a factor 10. Equivalently the line plot is scaled by factor of 10, resulting in a shrunken line plot. Either a transformation on the data side can induce a transformation on the visual side, or a transformation on the visual side indicates that there is also a transformation on the data side.

2.2.1 Category Theory

In this work, we propose that equivariance constraints can be expressed using category theory. Vickers et. al provide a brief introduction to category theory for visualization practitioners [?], but their work focuses on data, representation, and evocation, while this paper is aims to provide guidance on how the map from data to representation should be implemented.

3 Artist

The Artist $\mathcal{A}$[1] is a functor from data $\mathcal{E}$ to graphic $\mathcal{H}$.

$$A : \mathcal{E} \to \mathcal{H} \tag{5}$$

We formally define data and graphic as the categories $\mathcal{E}$ and $\mathcal{H}$. We develop these categories as analogues to fiber bundle (E, K, π, F), introduced in ??, and fiber bundle (H, S, π, D). Throughout this section, we assume that $\mathcal{E}$ is defined in terms of a fixed continuity and fiber space, for example a class of images or tables with the same schema. Similarly we assume that $\mathcal{H}$ is a stand in for a specific type of graphic, such as a scatter or line plot.

As introduced in ??, sets of open sets form the basis of topological spaces. We propose that we can express how the elements in our dataset are glued together by modeling that continuity as a topological space K, and we express the constraints on $K$by defining the analogues category $\mathcal{K}$.

Definition 3.1. The category of open sets $\mathcal{K}$ consists of

- *objects* all open sets $U_i \in \{U\}$ in the topological space [?], [?] $(K, \mathscr{T})$), including the empty set $\varnothing$ and the maximum set K.
- *morphisms* inclusion maps from a subspace to a larger space $\iota : U_i \hookrightarrow U_j$, which is equivalent to $U_i \subseteq U_j$ and

The objects U_i are a way to manage subsets of the data. For example, let there be a data value for each point along the interval $K = 0, 1]$. Since this function is continuous, there is a subset of the data defined along the open set $U_a = 0.2, 0.4)$. The open set U_a provides a unique way of identifying that subset.

maybe a small image here or when we introduce open sets showing what we mean?

Definition 3.2. The category $\mathcal{F}$ is a subcategory of an arbitrary category $\mathcal{C}$. $\mathcal{F}$ is a monoidal category, meaning it has one object F and a functor[2] $\otimes : \mathcal{F} \times \mathcal{F} \to \mathcal{F}$ [?].

The object F can be an object of any arbitrary category $\mathcal{C}$, which allows F to encode most data fields. For example, a lists of strings is an instance of an object in **Set**, networks are an instance of **Graph**, and images are vector spaces which are a specific type of topological space **Top**.

Definition 3.3. For each open set object U_i of category $\mathcal{K}$, there is a set $\Gamma(U_i, E)$. The elements of this set are the sections $\{\tau^j : U_i \to F_{U_i}\}_{j \in I}$ of the fiber bundle E over open set $_i$.

The sections $\Gamma(K, E)$ are called the global sections of E. [?], [?].

Each section is how we represent a unique dataset, where the set of sections Γ is the set of all datasets that have the same data fields in the F and continuity as encoded in$K$. For example, database tables that have the same schema and discrete index, as illustrated in Spivak [?].

For example, these functions could be the binary operations, group actions, and measurement scales discussed in ??. These functions could also be monoid actions, which are a way of applying partial order relations to data [?], such as to build multi-ranked indicators [?]

Definition 3.4. The category $\mathcal{E}$ consists of

- *object* the space of continuous[3]sections $\mathcal{O} : U_i \to \Gamma(U_i, E)$ which is a sheaf [?], [?].

[1]We call this transformation the artist because the Artist object in Matplotlib [?] is responsible for converting data to a prerender graphical object

[2]The functor $\otimes$ is a bifunctor because it takes as input the product of two categories [?]

[3]or piecewise continuous

- *morphisms* bundle maps E, E, fiber to itself and is the fiber map allowable, functions F to itself forms a monoid (one object category), F and it's allowable maps form a category, monoid could be monotonic functions, group actions, extending that to bundle E, interested in E to itself, which when restricted to fiber are category maps of fiber to itself, maps from sheaf to itself, that when restricted to fiber gives you fiber to itself, given bundle map E-¿E, then you can show that you have a sheaf map... Given E-¿E, and F-¿F, then there's a map from one sheaf to another. bundle map induces on level of sections induces on sheafs -¿ part of the definition of the presheaf
- *morphisms* E-¿E such that restricted to fiber it's the allowed maps, and restricted to base it's the inclusion map, sheaf to itself so is an endofunctor (category to itself)

Definition 3.5. We define the endofunctor Mon E as the structure preserving map which is the monoid. ...

equivariance is a special case of functions actions are a special case of actions

Definition 3.6. category of bundle maps, which include category of fiber maps, what are allowable of fiber to itself, ex translation and scales only ..., objects are a fiber, maps are fiber to fiber defined as their own category, E to V fibers changes

The objects of the data category $\mathcal{E}$ and graphic category $\mathcal{H}$ are the sheaves $\Gamma(K, E)$ and $\Gamma(S, H)$. An alternate notation is $\mathcal{O}(E)$ and $\mathcal{O}(H)$. The artist is a morphism of sheafs $\mathcal{O}(E)$ to $\mathcal{O}(H)$, which means it is by definition a natural transform [?]. As mentioned in **??** that the artist A transforms functions that act on data $f : E \to E$ to functions that act on graphics $: H \to E$ in a way in which the following diagram commutes

$$\begin{tikzcd} \mathcal{E} \arrow[r, "A"] \arrow[d, "f"] & \mathcal{H} \arrow[d, "g"] \\ \mathcal{E} \arrow[r, "A"] & \mathcal{H} \end{tikzcd} \tag{6}$$

meaning that, as described in **??**, the artist $A$is constructed such that $A(f(E)) = g(A(E))$, meaning a transformation of the data has a consistent equivalent transformation of the graphic. In **??**, we show a method of constructing the artist such that continuity and equivariance are preserved. We then use this formulation to guide the development of visualization library components in **??**.

Definition 3.7 (Category $\mathcal{H}$)**.**

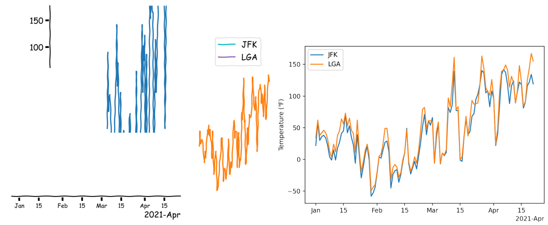
3.1 Union of Artists

do we define coherant visualizations as one with shared inclusions?

4 Constraints: Construction and formal properties of Artists

Definition 4.1. Following from the artist $A$is a special case of natural transformations

$$A : \Gamma(E, K) \nrightarrow \Gamma(H, S) \tag{7}$$



(a) Union of H (b) Artist with shared/harmonized μ

Fig. 5: Coherance?

between the profunctor objects $\Gamma(E), \Gamma(H)$ that preserves continuity and equivariance.

Natural transformations are functions that map functions between categories (functors) to other functors in a structure preserving way [?], [?], [?].

Definition 4.2. We define the natural transformation Artist A as the tuple $(\xi, \nu, Q, \mathcal{E}, \mathcal{V}, \mathcal{H})$ where

1) ξ is a continuity preserving functor
2) ν and Q are equivariance preserving functors
3) $\mathcal{E}$, $\mathcal{V}$, and $\mathcal{H}$ are profunctor categories of sheafs
4)

$$\begin{tikzcd} E \arrow[r, "\nu"] \arrow[dr, "\pi"'] & V \arrow[d, "\pi"] & \xi^*V \arrow[l, "\xi^*"'] \arrow[r, "Q"] \arrow[d, "\xi^*\pi"] & H \arrow[dl, "\pi"] \\ & K & S \arrow[l, "\xi"] & \end{tikzcd} \tag{8}$$

4.1 Data

We model data as sections of a fiber bundle (E, π, K, F). We encode the continuity of the data as the base space K. does this go in intro? The fiber space F is the space of all possible values of the data **??**. We model the data as the section τbecause, as described in **??**, the section is the map from the indexing space $K$to the space of possible data values F. Spivak's notation, as discussed in **??**, also allows for associating elements in a section with the field it comes from. This allows for field based selection of values, while inclusion allows for continuity (index) based selections.

One example of encoding data as a section of a fiber bundle is illustrated in **??**. In this example, the data is a not totally decided yet table of weather station data. Here we are interested in the time series of temperature values in the data, so we encode the continuity as the 1D interval K. In this multivariate data set, the fields we want to visualize are `time`, `temperature`, and `station`. The fiber space F is the cartesian cross product of the fibers of each field

$$F = F_{\mathtt{time}} \times F_{\mathtt{temperature}} \times F_{\mathtt{station}}$$

where each field fiber is the set of values that are valid for the field:

$$\begin{aligned} F_{\mathtt{time}} &= \mathbb{R} \\ F_{\mathtt{temperature}} &= \mathbb{R} \\ F_{\mathtt{station}} &= \{s_0, s_1, \cdots, s_i, \cdots, s_n\} \end{aligned}$$

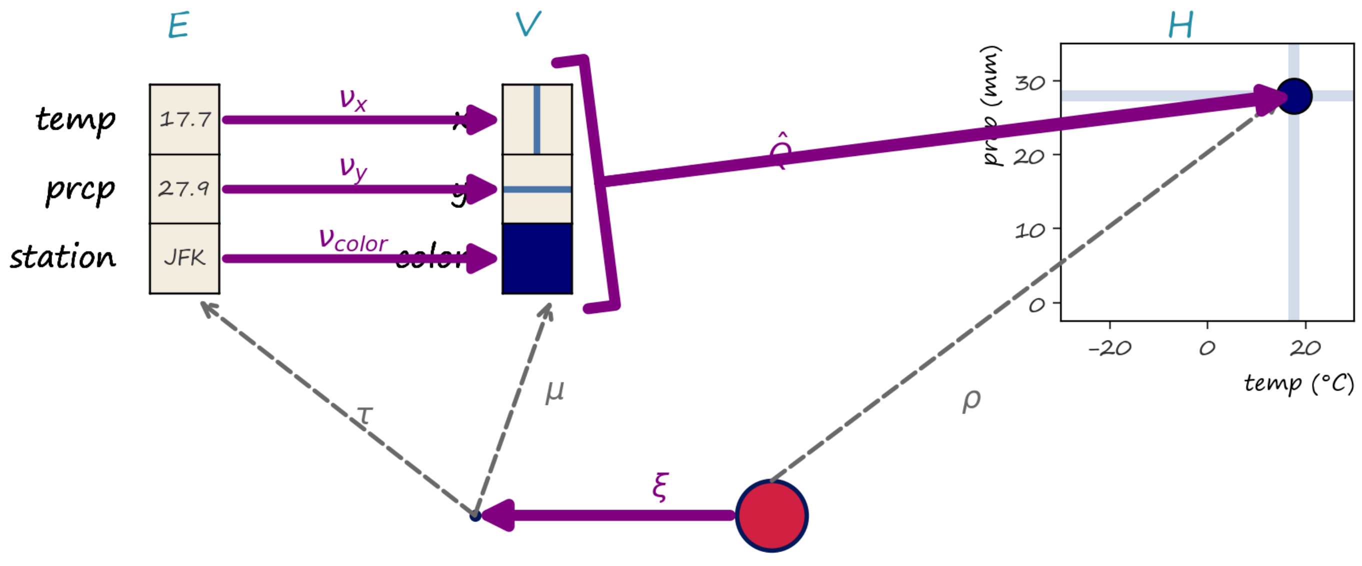


Fig. 6

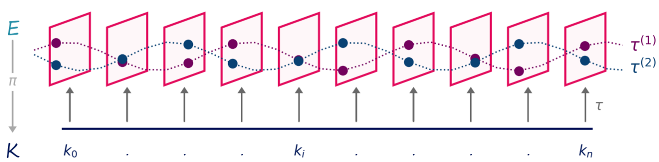

Fig. 7: replace with more concrete

The section τ is the abstraction of the data being visualized. The section at a point $k \in K$ in the base space returns a value from each field in the fiber.

$$\tau(k) = ((time, t_k); (precipitation, p_k); (station\ name, n_k))$$

4.2 Graphic

The object of the graphic category $\mathcal{H}$ is the fiberbundle H. The bundle H has the same structure as the data bundle E

$$\begin{tikzcd} D \arrow[r, hook] & H \arrow[d, shift right, "\pi"'] \\ & S \arrow[u, shift right, bend right, "\rho"'] \end{tikzcd} \tag{9}$$

with a fiber space D embedded in the total space H and a section map $\rho : S \to H$. The attributes of the graphic bundle (H, π, D, S) encode attributes of the graphic and display space

base space S continuity of display space (e.g. screen, 3D print)

fiber space D attributes of the display space (e.g a pixel = (x,y,r,g,b,a))

section ρ graphic generating function

.

We represent the graphic output as a fiber bundle because it is an abstraction that is generalizable to various output mediums (screens, 3D prints) and types of graphics. In this work, H assumes the the display is an idealized 2D screen and ρ is an abstraction of rendering. For example, ρ can be a specification such as PDF [?], SVG [?] or an OpenGL scene graph [?], or a rendering engine such as Cairo [?] or AGG [?].

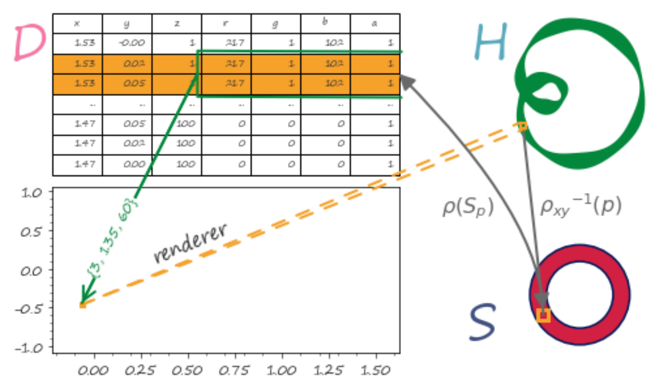

Fig. 8

Example 4.1. As illustrated in ??,

4.3 Visualization Library Components

4.3.1 Graphic to Data: ξ

$$\begin{tikzcd} E \arrow[d, "\pi"'] & H \arrow[d, "\pi"'] \\ K & S \arrow[l, "\xi"'] \end{tikzcd} \tag{10}$$

The functor ξ is a deformation retract, which means.... [?], [?]

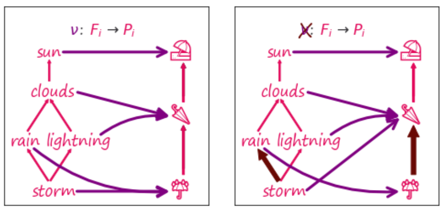
4.3.2 Visual Bundle V

$$\begin{tikzcd} P \arrow[r, hook] & V \arrow[d, "\pi"', shift right] \\ & K \arrow[u, bend right, "\mu"', shift right] \end{tikzcd} \tag{11}$$

4.3.3 Data to Visual Encodings: ν

Visual encoding functions ξ are functors because they are expected to preserve structure on the data and visual side, as discussed in ??.

This constraint is expressed in our construction of ν



(a) Artists with shared μ_i renderered correctly (b) Artists without shared μ_i

Fig. 9: Simulation results for the network.

$$\{\nu_0, \dots, \nu_n\} : \{\tau_0, \dots, \tau_n\} \mapsto \{\mu_0, \dots, \mu_n\} \tag{12}$$

We enforce the equivariance constraint

$$\begin{tikzcd} E_i \arrow[r, "\nu_i"] \arrow[d, "m_r"'] & V_i \arrow[d, "m_\nu"] \\ E_i \arrow[r, "\nu_i"] & V_i \end{tikzcd} \tag{13}$$

One advantage of expressing the data to visual encoding ν_i as a functor from data fiber F_i to P_i is that it lets us formally express that encodings are bound to data and therefore should be consistent across views, as proposed by Hullamn and Qu [?].

4.3.4 Visual to Graphic: Q

Visual encodings to something like marks

Fig. 10: rework this as a commutative box w/ the r in E row associated w/ this qhat(k)

5 Case Study

We implement the **arrows** in ??. `axesArtist` is a parent artist that acts as a screen. This allows for the composition described in ??

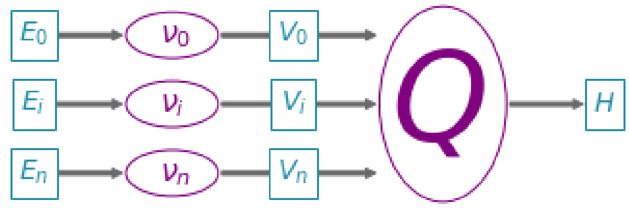


Fig. 11: add in xi!

5.1 A

```
for local_tau in axesArtist.artist.data.query(screen_bounds, dpi):
    mu = axesArtist.artist.graphic.mu(local_tau)
    rho = axesArtist.artist.graphic.qhat(**mu)
    H = rho(renderer)
```

where the artist is already parameterized with the ξ functions and which fibers they are associated to:

5.1.1 ξ

5.1.2 ν

5.1.3 $\hat{Q}$

6 Discussion

6.1 Limitations

6.2 future work

7 Conclusion

The conclusion goes here.

Appendix A Rendering: ρ

Appendix B Manufacturing $\hat{Q} \leftarrow Q$

$$\begin{tikzcd} E \arrow[r, "\nu"] \arrow[dr, "\pi"'] & V \arrow[d, "\pi"', shift right] & \xi^*V \arrow[l, "\xi^*"'] \arrow[r, "Q"] \arrow[d, "\xi^*\pi"', shift right] & H \arrow[dl, "\pi"] \\ & K \arrow[u, bend right, "\mu"', shift right] & S \arrow[l, "\xi"'] \arrow[u, bend right, "\xi^*\mu"', shift right] & \end{tikzcd} \tag{14}$$
